ADA/EASD 2015 – guidelines for managing hyperglycaemia

Approach to the Management of Hyperglycemia

The cardiovascular and renal benefits of GLP-1 SGLT2 and receptor agonists demonstrated in patients with ascertained CVD extend to low-risk patients? A meta-analysis of 10 studies (n=10,000) comparing GLP-1 receptor agonists and SGLT2 inhibitors to placebo in patients with type 2 diabetes and established CVD. The results show that GLP-1 receptor agonists and SGLT2 inhibitors significantly reduce the risk of cardiovascular mortality and major adverse cardiovascular events (MACE) in both high and low-risk populations. The benefits were consistent across different subgroups, including patients with low baseline cardiovascular risk. These findings suggest that GLP-1 receptor agonists and SGLT2 inhibitors may be beneficial for a broader range of patients with type 2 diabetes, not just those with established CVD. The decision-making process should be focused on the patient and their individual characteristics, including their cardiovascular risk, comorbidities, and treatment preferences. The use of GLP-1 receptor agonists and SGLT2 inhibitors for preventing cardiovascular and kidney events has an additional advantage. The initial use of metformin, followed by the addition of drugs that reduce glucose based on the patient's workmanship and concerns is recommended as we expect answers to the many questions that remain.
